

Micro Security Project 🐼

Secrets... Secrets... Secrets... Every company has them, every hacker wants to know them.

TruffleHog is a lightweight tool used to scan for secrets, such as API keys, passwords, or other sensitive information, in code repositories.

While TruffleHog is traditionally used in CI/CD pipelines as part of DevSecOps practices, this project is aimed at those who are just getting started with security scanning. The focus will be on how to use TruffleHog on a single static repo.

I will cover:

- How to set it up (**Micro Project**)
- CV Challenge Pointers (**You should do this**)

So how can you easily set this up?

You'll need a few things like Docker and Basic Bash commands knowledge but I'll walk you through it all...

Step One: Install Docker

Install docker. This can be done with a few simple commands:

```
## Update your system ##
```

```
sudo apt-get update
```

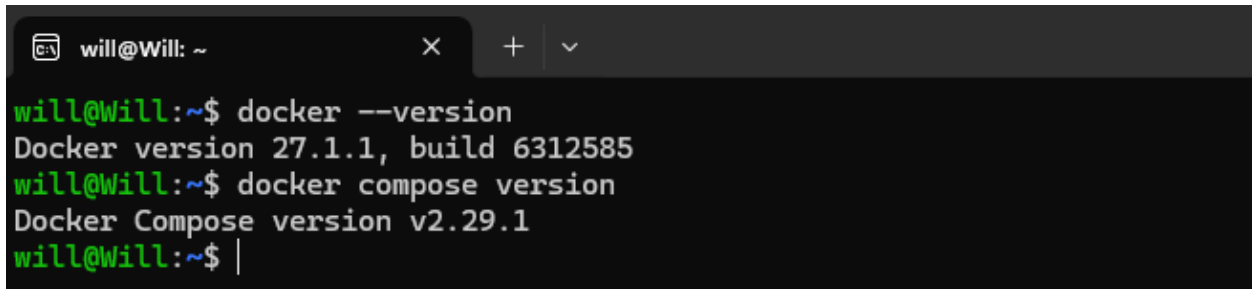

I recently found a new quick way of installing docker.

```
## Download script and run ##
curl -fsSL https://get.docker.com -o get-docker.sh
sudo sh get-docker.sh
```

The above is an official script that will do all the work for you. If you are paranoid about running a random script, feel free to look inside it.

Finally check you have docker & docker compose installed correctly

```
## Version Checker ##
docker --version
docker compose version
```

A terminal window with a dark background. The title bar shows 'will@Will: ~' and window controls. The terminal output shows the user running 'docker --version' which returns 'Docker version 27.1.1, build 6312585', then 'docker compose version' which returns 'Docker Compose version v2.29.1'. The prompt is currently at 'will@Will:~\$ |'.

```
will@Will:~$ docker --version
Docker version 27.1.1, build 6312585
will@Will:~$ docker compose version
Docker Compose version v2.29.1
will@Will:~$ |
```

Step Two: Get Trufflehog

Remember, we are using Docker for this project so run the following

`docker run --rm -it -v "$PWD:/pwd" trufflesecurity/trufflehog:latest github --repo`
https://github.com/trufflesecurity/test_keys

```
docker run --rm -it -v "$PWD:/pwd" trufflesecurity/trufflehog:latest github --
repo https://github.com/trufflesecurity/test_keys
```

Command Breakdown:

docker run: This runs a Docker container.

--rm: Automatically removes the container once it stops, cleaning up after execution.

-it: Runs the container in interactive mode with a terminal (-i for interactive and -t for terminal).

-v "\$PWD:/pwd": Mounts the current working directory (\$PWD) on your host machine to the /pwd directory inside the Docker container. This allows the container to access files in your local directory.

trufflesecurity/trufflehog:latest: Specifies the Docker image to run, in this case, the latest version of the trufflesecurity/trufflehog image.

github --repo https://github.com/trufflesecurity/test_keys: Runs the TruffleHog tool inside the container to scan the specified GitHub repository (https://github.com/trufflesecurity/test_keys) for sensitive information like secrets.

You should see something like this pop up on the command line, followed by some test results from the example repo.

 TruffleHog. Unearth your secrets. 

Step Three: Target our own Git Repo

We now want to run TruffleHog against our own repo, so let's run that command again but this time swap out the example repo with yours. If you don't have one, follow my guide here: [Set up your own Repo!](#)

As you can see I've swapped out the example one with my own (Feel free to Fork this):

`docker run --rm -it -v "$PWD:/pwd" trufflesecurity/trufflehog:latest github --repo https://github.com/wjpearce-git/Basic-AWS-Networking`

```
docker run --rm -it -v "$PWD:/pwd" trufflesecurity/trufflehog:latest github --
repo https://github.com/wjpearce-git/Basic-AWS-Networking
```

Trufflehog will run against this repo and apart from some metadata about the scan, no secrets will be found.

Step Four: Let's find some secrets

What if I put a fake user pass and IP in my repo though?!

Let's try that, I'll create a new branch with:

`git checkout -b thogtest`

```
git checkout -b thogtest
```

If you've looked at my repo, you'll see I'm working with Terraform so let's add the following "Bad" code into the **variables.tf** file:

```
##### Trufflehog Test #####
variable "creds" {
  description = "Testing Server"
  default = "http://user:password@192.168.0.1:8080"
}
```

Let's push and merge that:

```
git add .
git commit -am "wip: testing secret detection"
git push --set-upstream origin thogtest
```

Now run the Docker and Trufflehog again

```
$ docker run --rm -it -v "$PWD:/pwd" trufflesecurity/trufflehog:latest github --repo https://github.com/wjpearce-git/Basic-AWS-Networking
🐷🐷 TruffleHog. Unearth your secrets. 🐷🐷

2024-09-11T11:01:15Z info-0 trufflehog running source {"source_manager_worker_id": "3YpLe", "with_units": false, "target_count": 0, "source_manager_units_configurable": true}
2024-09-11T11:01:16Z info-0 trufflehog Completed enumeration {"num_repos": 1, "num_orgs": 0, "num_members": 0}
2024-09-11T11:01:16Z info-0 trufflehog scanning repo {"source_manager_worker_id": "3YpLe", "repo": "https://github.com/wjpearce-git/Basic-AWS-Networking.git"}
Found unverified result 🐷🐷
Verification issue: dialing local IP addresses is not allowed
Detector Type: URI
Decoder Type: PLAIN
Raw result: http://user:password@192.168.0.1:8080

Email: willpearce101 <wormhole101@protonmail.com>
File: variables.tf
Line: 39
Link: https://github.com/wjpearce-git/Basic-AWS-Networking/blob/0ba2cb35bc06c3899fbd4e269cfade4a7a4542cd/variables.tf#L39
Repository: https://github.com/wjpearce-git/Basic-AWS-Networking.git
Timestamp: 2024-09-11 11:00:27 +0000

2024-09-11T11:01:16Z info-0 trufflehog finished scanning {"chunks": 18, "bytes": 5204, "verified_secrets": 0, "unverified_secrets": 1, "scan_duration": "890.961285ms", "trufflehog_version": "3.81.10"}
```

As you would expect, Trufflehog has picked up on this and provided the issue with the line and file.

🎉 Congrats you've found your first secret! 🎉

Trufflehog's capabilities go well beyond what we've done here.

CV Challenge

If you're up for a challenge I recommend trying **AND DOCUMENTING** the following:

- Scan an S3 bucket for verified keys - Remember you'll need to set up an AWS Account.
- Scan individual files or directories
- Finally, set up Trufflehog to run when a PR is created using GitHub actions so that only the Source Code in the PR is scanned

Here's a hint to get you started:

```
name: TruffleHog PR Scan
on: pull_request
jobs:
  scan:
    runs-on: ubuntu-latest
    steps:
      - name: Checkout code
        uses: actions/checkout@v2
      - name: Run TruffleHog
        run: docker run --rm -v ${GITHUB_WORKSPACE}:/pwd
        trufflesecurity/trufflehog:latest filesystem /pwd
```
